

## Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

IV. Observations on the Satellites of Jupiter and Saturn, made with the same Telescope. By John Hadley, Esq. F. R. S. Extracted from the Minutes of the Royal Society, Apr. 6. 1721.

R. Hadley gave the Society a Relation of some of the most remarkable Observations, which he had made with his Reslecting Telescope, before he

presented it to the Society.

In observing Jupiter's Satellites he has seen distinctly the Shadows of the first and third Satellites cast upon the Body of the Planet; Mr. Folkes and Dr. Jurin, being present, affirmed, that Mr. Hadley had likewise shewn them the Shadow of the third Satellite

through the same Telescope.

In observing Saturn the last Spring, at a Time when that Planet was about 15 Days past the Opposition, he saw the Shade of the Planet cast upon the Ring, and plainly discerned the Ring to be distinguished into two Parts, by a dark Line, concentric to the Circumference of the Ring. The outer or upper Part of the Ring seemed to be narrower than the lower or inner Part, next the Body, and the dark Line, which separated them, was stronger next the Body, and fainter on the outer Part towards the upper Edge of the Ring. Within the Ring he discerned two Belts, one of which cross'd Saturn close to its inner Edge, and seemed like the Shade of the Ring upon the Body of Saturn; but when he considered the Situation of the Sun, in respect

to the Ring and Saturn, he found that Belt could not arise from such a Cause.

He fays, that at Times he has feen with this Telefcope three different Satellites of *Saturn*, but could never have the Fortune to fee all five.

Aug. 1723. Mr. Hadley adds, that he has feveral Times feen the Shadow of the first, second, and third Satellites of Jupiter pass over the Body of that Planet, and that he has seen the first and second appear, as a bright Spot upon the Body of Jupiter, and has been able to keep Sight of them there for about a Quarter of an Hour, from the Time of their entring on his Limb.

Jupiter's Satellites have of late Years been so situated, with regard to the Earth and Jupiter, that he has not had sufficient Opportunity of observing the Transit of the fourth Satellite, or of its Shadow.

The dark Line on the Ring of Saturn, parallel to its Circumference, is chiefly visible on the Ansa, or Extremities of the Elliptick Figure, in which the Ring appears; but he has several Times been able to trace it very near, if not quite round; particularly in May, 1722, he could discern it without the Northern Limb of Saturn, in that Part of the Ring, that appeared beyond the Globe of the Planet. The Globe of Saturn (at least towards its Limb) reslects less Light than the inner Part of the Ring, and he has sometimes distinguish'd it from the Ring by the Difference of Colour.

The dusky Line, which in 1720 he observed to accompany the inner Edge of the Ring cross the Disk, continues close to the same, though the Breadth of the Ellipse is considerably encreas'd since that Time.
